B4 PROTEIN FOR INDUCING CELL DEATH

BACKGROUND OF THE INVENTION

(a) Field of the Invention

The invention relates to a pharmaceutical agent(s) to induce cell death in any diseases which involve inappropriate cell survival.

(b) Description of Prior Art

Replication of human adenoviruses in terminally differentiated epithelial cells requires an efficient mechanism to induce cellular DNA synthesis to permit replication of viral DNA and production of progeny virus. Human adenoviruses infect and kill epithelial cells very efficiently. Cell death occurs by apoptosis and virus spread occurs through endocytosis by sur-Products of early region 1A (E1A) rounding cells. induce cell DNA synthesis and are largely responsible for cell transformation by adenoviruses. ElA produces two major mRNAs of 13S and 12S which encode proteins of 289 and 243 residues (289R and 243R, respectively) that are identical except for a central 46-amino acid sequence, termed conserved region 3 or CR3. Two additional regions present in the common sequence encoded by exon 1 of both ElA mRNAs are also conserved in all human serotypes and have been termed CR1 and CR2 (see ElA products induce DNA synthesis through Fig. 1A). complex formation between CR2 and CR1 and the retinoblastoma tumor suppressor pRE and related pl07 and pl30 proteins, or between the amino terminus and CR1 and the transcriptional modulator p300 and possibly related proteins (Corbeil, H.B. et al., 1994, J. Virol., 68:6697-6709). ElA-289R also activates expression of the early viral transcription units E2, E3 and E4, and certain cellular genes at least in part through interactions with transcription factors and basal transcription machinery requiring CR3 (Teodoro, J.G., et al.,

10

35

1995, Oncogene, 11:467-474). In addition to Ck3, transactivation of the E4 promoter has also been shown to rely to some degree on two regions encoded by the second exon of 13S mRNA, termed auxiliary regions 1 and Production of stably transformed 2, or AR1 and AR2. cells requires early region 1B (E1B) which encodes polypeptides of 19 and 55kDa that are individually capable of cooperating with ElA via separate but additive pathways (McLorie, W. et al., 1991, J. Gen Virol., 72:1467-1471).

Considerable evidence indicates that a major function of EIB proteins in lytic infection and cell transformation is to suppress cytotoxic effects and apoptosis induced by expression of ElA. Without ElB, the toxicity of ElA products results in the death of 15 ElA-transformed cells and a reduction in the yield of progeny due to the early demise of productively infected cells. ElA proteins can cause apoptosis by a process mediated by the tumor suppressor p53 (Teodoro, J.G., et al., 1995, Oncogene, 11:467-474), which con-20 trols growth arrest and programmed cell death pathways (Teodoro, J.G., et al., 1995, Oncogene, 11:467-474). Expression of ElA products results in the elevation of The 55kDa ElB protein binds to p53 and p53 levels. blocks both p53-mediated activation of gene expression 25 and apoptosis (Teodoro, J.J., et al., 1994, J. Virol., 68:776-786). The 19kDa ElB protein appears to suppress apoptosis by a mechanism that is functionally analogous to that of the cellular proto-oncogene product Bc1-2 (Nguyen, M. et al., 1994, J. Biol. Chem., 269:16521-30 Cells infected with adenovirus mutants which fail to express the 19kDa protein display enhanced cytotoxicity and extensive degradation of both cellular and viral DNA into nucleosome sized fragments (McLorie, W. et al., 1991, J. Gen Virol., 72:1467-1471; Teodoro,

"人人的"他们在是是不是一个"。 第一个

建筑

会は、1982年の1

30

J.G., et al., 1995, Oncogene, 11:467-474). At later times, even in the presence of ElB proteins, infected cells suffer apoptotic death and viral progeny spread to neighboring cells through endocytosis of cell fragments. In addition to the induction of DNA synthesis and cell transformation, the large 289-residue (289R) ElA protein also transactivates expression of all early viral genes, including early regions 1A, 1B, 2, 3 and 4 (reviewed in Teodoro, J.G., et al., 1995, Oncogene, 11:467-474).

Recently both our group showed that in the absence of ElB, ElA products also induce p53-independent apoptosis (Teodoro, J.G., et al., 1995, Oncogene, 11:467-474). Our results indicated that such apoptotic cell death was only induced by the 289R ElA protein. Furthermore, when p53-null mouse cells constitutively expressing ElA products were infected by an adenovirus vector lacking the entire ElA and ElB coding regions but containing early regions E2, E3 and E4, rapid cell death due to apoptosis was observed (Teodoro, J.G., et al., 1995, Oncogene, 11:467-474). We have shown that 289R induces apoptosis in p53-null mouse and human and that such p53-independent cell death requires the expression of another early viral gene (Teodoro, J.G., et al., 1995, Oncogene, 11:467-474). Genetic analysis indicated that neither E2 nor E3 products were necessary and that one or more E4 proteins are responsible (Marcellus, S. et al., 1996, J. Virol., E4 encodes several mostly unrelated proin press). teins whose functions are only partially understood. These results indicated that the role of ElA-289R may be to transactivate expression of an additional early transcript whose product actually induces p53-independent apoptosis. In the present studies we report that

one or more E4 gene products appear to be responsible for such cell killing.

It would be highly desirable to be provided with a pharmaceutical agent for induction of apoptosis when such induction is useful in the treatment of human diseases which involve inappropriate cell survival.

SUMMARY OF THE INVENTION

15

20

25

35

二十年 門口が上げ 知道 あって か 日本 日本

In accordance with the present invention, a genetic approach to identify the role of individual E4 proteins in the induction of p53-independent apoptosis was used. Our results indicated that the E4orf6 protein is responsible. Thus E4orf6 is a powerful inducer of p53-independent cell death.

One aim of the present invention is to develop E4orF6 as a pharmaceutical agent for induction of apoptosis when such induction is useful in the treatment of human diseases which involve inappropriate cell survival.

In accordance with the present invention there is provided a pharmaceutical agent for induction of apoptosis for the treatment of human diseases which involve inappropriate cell survival, which comprises E4orf6, an analog or a biologically active fragment thereof.

In accordance with the present invention there is also provided a pharmaceutical composition for the treatment of human diseases which involve inappropriate cell survival, which comprises a therapeutical amount of E4orf6, an analog or a biologically active fragment thereof in association with a pharmaceutical carrier.

In accordance with the present invention, the expression "diseases which involve inappropriate cell survival" include, without limitation, diseases caused by HIV, herpes and/or other viral infections, Alzheimer's, cancer, arthritis, lupus among others.

The pharmaceutical agent of the present invention allows for the selective killing of cells that are prevented from dying by a virus or as a consequence of a disease state. Thus, the pharmaceutical agent of the present invention only kills the inappropriately surviving cells, such as cancer cells or viral infected cells. This results in a substantially side effect free therapy for the patient.

The pharmaceutical agent of the present inven10 tion includes, without limitation, any adenovirus of
any serotype E4 death protein (E4-ADP) products, fragment thereof and mimetic peptides of this protein products.

DETAILED DESCRIPTION OF THE INVENTION

In the absence of ElB, the 289- and 243-residue (289R and 243R) ElA products of human adenovirus type 5 (Ad5) induce p53-dependent apoptosis. However, our group has shown recently that the 289R ElA protein is also able to induce apoptosis by a p53-independent mechanism (Teodoro et al., 1995, Oncogene, 11:467-474). Preliminary results suggested that p53-independent cell death required expression of one or more additional adenovirus early gene products. Here we show that both the ElB-19kDa protein and cellular Bcl-2 inhibit or significantly delay p53-independent apoptosis. Neither early regions E2 or E3 appeared to be necessary for Analysis of a series of ElA mutants such cell death. indicated that mutations in the transactivation domain and other regions of ElA correlated with ElA-mediated transactivation of E4 gene expression. Furthermore, p53-deficient human SAOS-2 cells infected with a mutant which expresses ElB but none of the E4 gene products remained viable for considerably longer times than those infected with wt Ad5. In addition, an adenovirus vector lacking both El and E4 was unable to induce DNA degradation and cell killing in ElA-expressing cell These data showed that an E4 product is essential for ElA-induced p53-independent apoptosis.

Cells and viruses

10

15

Human Saos-2 cells (ATCC HTB 85) and 10(1) mouse embryo fibroblast-derived cells which are both deficient for p53 expression were cultured on 60mm-diameter dishes (Corning Glass Works, Corning, N.Y.) in

Dulbecco's modified MEM (D-MEM) supplemented with 10% fetal calf serum (FCS) as were both NIH-3T3 and CHO The cell line Saos-2/Bcl-2(3g4) which stably expresses Bcl-2 was derived for this study from Saos-2 cells by selection with G418 as was the control line Saos-2/Neo(2a2). Al.A3, Al.A6 and Al.Al2 mouse embryo fibroblast cell lines expressing Ad5 ElA proteins, and Hy.A3 hygromycin-selected control lines, have been described previously (Lowe, S.W. et al., 1994, Proc. 10 Natl. Acad. Sci. - U.S.A., 91:2026-2030), and were cultured in D-MEM containing 10% FCS and 100 µg/mL of hygromycin. Normally cells were infected with mutant or wild-type (wt) Ad5 at a multiplicity of 100 pfu per Ad5 ElA mutants are illustrated in Fig. 1A and include deletion mutants dlll01 (residues 4-25 deleted), dlll43 (38-60), dlll07 (lll-123), dlll08 (124-127), d11143/08 (38-60 plus 124-127) and d11132 (224described previously which have all been (Marcellus, S. et al., 1996, J. Virol., in press). Proteins encoded by some of the mutants used in the 20 present studies have been presented, including the residues removed in deletion mutants. CR1, CR2, CR3, AR1 and AR2 have also been indicated. A new E1A mutant was constructed as termed AR1 /ElB-, which lacks the entire ARl region (residues 189-200) and also fails to express ElB products. Mutant AR2 / ElB was generated by introducing dlll32, which lacks residues 224-?38, into a background that fails to express ElB proteins. Mutant AR1 AR2 ElB represents a combination of the 30 latter two mutants. Additional ElA mutants containing single amino acid substitutions at various sites within CR3 were produced by subcloning appropriate restriction enzyme fragments from mutant ElA cDNA plasmids into genomic viral DNA, followed by rescue into virus to form mutants AD147VL (Val-147 converted to Leu),

名称がかかって言語の問題が記者でいたが

AD177CS, and AD185SG. All other mutants have been summarized in Fig. 1B. A list providing the names and defects of ElB and other mutants has been presented. Two were produced previously by our group (McLorie, W. et al., 1991, J. Gen Virol., 72:1467-1471) and fail to express ElB proteins of 19kDa (originally called E1B/19K) and pm1716/2072 but now E1B/55K). pm2019/2250, now (originally 12S/ElB (originally d1520ElB) produces only the ElA-243R protein encoded by the 12S mRNA and no ElB prod-Mutant ElB which expresses both major ElA products but neither the 19kDa or 55kDa ElB species was described previously (Teodoro, J.G., et al., and a similar mutant 11:467-474), Oncogene, expresses only 289R in the absence of ElB, termed 13S/ElB, was prepared for the present studies. series of ElA mutants (dll101/E1B, dll107/E1B, AD147VL/E1B, etc.) which express no E1B products was also produced by introducing ElA mutations into mutant which expresses both 289R and 243R ElA products but no ElB (Teodoro, J.G., et al., 1995, Oncogene, The presence of mutations in all mutants 11:467-474). was confirmed by DNA sequencing, restriction enzyme digestion, or Southern blotting. Ad5 vectors used in this study included AdLacZ in which the El (FlA + ElB) region was replaced with the E. coli gene lacZ under the CMV promoter, and Ad5dl70-8 which was generated by cotransfection of plasmids pAB7 and pBHG10 and which lacks both El and the entire E3 region. Adenovirus 30 vector AdRSVβgal.11 which lacks the entire El and E4 regions was a gift of Douglas Brough. In addition, some experiments were carried out with human adenovirus type 2 (Ad2) mutant dll019 which contains deletions that eliminate expression of all E4 products and which was propagated on W162 monkey cells, as described pre-

15

MONOCOL SCHOOLS

Low molecular weight DNA was isolated from mock- or Ad5-infected cells as described in Teodoro et For Oncogene, 11:467-474). (1995, cells experiments, 60mm-diameter plates of 10 harvested at 40 h post-infection and lysed in promase lysis buffer comprised of 10mM Tris-HCl containing 5mM EDTA, 100mM NaCl, and 1 mg/mL (w/v) pronase to which SDS was added to 0.5% (w/v). lysates were incubated at 37°C for 2 h and NaCl was added to a final concentration of lM. Samples were then incubated overnight at 4°C and centrifuged at Extracted nucleic acids were 15,000 x g for 30 min. treated with RNAase A and analyzed on 1% agarose gels stained with ethidium bromide.

Cell viability assays

Cells were infected with wt or mutant virus in 24-well plates containing cells at about 80% conflu-At various times following infection adherent and non-adherent cells were pooled and viability was assessed by Trypan Blue™ exclusion. At least 300 cells were counted at each time point.

Measurement of BlA-mediated transactivation of adenovirus E4 promoter

Transactivation assays were performed using NIH 3T3 or CHO cells plated at a density of 2 x 10^5 cells on 60 mm-diameter dishes. The E4 reporter plasmid was E4-CAT containing the E4 promoter upstream of the chloramphenicol acetyltransferase (CAT) gene. co-transfections were performed by the calcium phosphate precipitation method using 2.5 µg of reporter

plasmid DNA and 2.5 μg of DNA from plasmids expressing wt or mutant ElA products as described in Marcellus et al., 1996. Cells were glycerol shocked after 12h and then harvested 36 h later. CAT assays were performed using cell extracts containing equal amounts of β -galactosidase activity. The amount of activity was quantified from TLC plates using a Fujix Bas 2000 Phosphorimager.

10 BlA-induced p53-independent apoptosis is inhibited by both the BlB-19kDa protein and cellular Bc1-2

Previous studies indicated that whereas both major Ad5 ElA products could induce apoptosis in cells expressing p53, only the 289R ElA protein could do so in cells lacking p53 (Teodoro, J.G., et al., 1995, Oncogene, 11:467-474). Fig. 2 shows the pattern of DNA fragmentation in p53 mouse 10(1) cells infected by various Ad5 mutants. 10(1) cells which fail to express p53 were infected with various Ad5 mutants, or they were mock-infected, and at 40 h p.i., low molecular weight DNA was analyzed by agarose gel electrophoresis. The contents of individual lanes are as indicated in Fig. 2. Extracts from mock-infected cells (lane 1) and those infected with wt Ad5 (lane 2) which expresses ElB products displayed reduced levels of extracted low molecular weight DNA and little or no degraded DNA, as did those from cells infected with mutant ElB/55K (lane 4) which produces the ElB-19kDa protein but not the ElB-55kDa product. With cells infected with mutant ElB which synthesizes both the 289R and 243R ElA proteins but which produces no ElB products (lane 6), large amounts of DNA were extracted and high levels of nucleosome-sized DNA fragments were evident. results were also obtained with cells infected with ElB/19K (lane 5) which produces the ElB-55kDa species but not the 19kDa protein. Induction of DNA degradation

25

30

in these p53 cells did not occur following infection with 125/E1B (lane 3) which produces only E1A-243R and no E1B, but it did occur with 135/E1B (lane 7) which yields only E1A-289R in the absence of E1B products. Thus as shown previously, E1A-289R but not 243R induces p53-independent apoptosis in the absence of E1B proteins. In addition the results indicated that the E1B 19kDa polypeptide but not the 55kDa E1B product is able to protect against apoptosis induced by E1A in the absence of p53.

10

To examine the specificity of inhibition of apoptosis further, studies were conducted to determine if the cellular Bcl-2 protein is also able to prevent p53-jadependent apoptosis as several previous studies had snown that Bc1-2 and the BlB-19kDa protein may be functionally similar (Nguyen, N. et al., 1994, J. Biol. Chem., 269:16521-16524). Human Saos-2 cells which are defective for synthesis of p53 were transfected with CUNAs encoding the human Bcl-2 protein and the neomycin 20 resistance marker and several cell lines were selected using G418. One such Bc1-2 expressing clone, termed Saos-2/Bc1-2(3g4), and a control SAOS-2 clone, SAOS-2/neo(2a2) selected only for resistance to G418, were infected with wt Ad5, mutants 12S/ElB or ElB/19K, or were mock-infected, and cell viability assays were 25 conducted at various times after infection. In Fig. 3, p53-deficient human Saos-2/neo(2a2) cells (panel A) or Saos-2/Bc1-2(3g4) which express human constitutively (panel B) were mock-infected or infected with wt, ElB/19K or 12S/ElB and were tested for 30 viability by a Trypan Blue™ exclusion assay at various times following infection, as described above. Results have been presented as the logarithm of the % viable cells, and symbols are as indicated in Fig. 3. Fig. 3A shows that SAOS-2/neo(2a2) control cells were killed by

the ElB/19K virus that expresses ElA-289R, but those infected with wt or 12S/ ElB remained almost as viable as mock-infected cells during the test period. Fig. 3B shows that with Saos-2/Bcl-2(3g4) cells which stably express high levels of Bcl-2, little cell death was induced by the ElB/19K virus. Similar results were obtained with three other control and Bcl-2 producing SAOS-2 cell lines. Thus like the ElB-19kDa protein, Bc1-2 also blocks ElA-induced p53-independent apoptosis.

Role of ElA domains in p53-independent apoptosis.

25

30

To investigate the regions of ElA products involved in causing p53-independent cell death, p53 mouse 10(1) cells were infected with Ad5 mutants which fail to express ElB and which harbor a variety of defects at various regions of the ElA molecule. Extracts were harvested and analyzed on gels to determine the extent of degradation of low molecular weight DNA. In Fig. 4, an experiment in p53-deficient 10(1) cells similar to that described in Fig. 2 was performed using a series of Ad5 ElA mutants defective in expression of ElB products. The contents of individual lanes are as indicated in Fig. 4. Fig. 4 shows that again (lane 3) induced DNA degradation mutant ElB/19K whereas such did not occur with wt Ad5 (lane 2) or mock-infected cells (lane 1). Mutants which affected the ElA transactivation function associated with CR3 all failed to induce DNA degradation. These included 12S/ElB (lane 8), and point mutants AD147VL/ElB, AD171CS/E1B and AD185SG/E1B (lanes 9 to 11, respectively) which carry single residue substitutions at critical residues in CR3 that eliminate ElA transactivation activity. In addition, deletion of ARl or both AR1 and AR2 (AR1 /E1B and AR1 /AR2 /E1B in lanes 35 12 and 14) also eliminated DNA degradation whereas

問題を対する。

removal of AR2 alone (AR2 /E1B in lane 13) had little Interestingly, mutants in CR2 which eliminate complex formation with pRB and related proteins (dlll07/ElB and dlll08/ElB in lanes 5 and 6) had no effect on the induction of DNA degradation, whereas those that eliminated binding of p300 by removal of the N-terminus (dlll01/ElB in lane 4) or a portion of CR1 as well as the pRB binding site (dll143/08/E1B in lane 7) no longer caused this effect. suggested that ElA-induced p53-independent apoptosis required the CR3 transactivation domain, AR1, and the regions necessary for binding of p300 but not pRBrelated proteins. Fig. 5 shows that similar results were obtained with these mutants in cell killing An experiment similar to that described in Fig. 3 was carried out in SAOS-2 cells infected with various ElA mutants defective in expression of ElB products. Results have been presented as the logarithm of the % viable cells, and symbols are as indicated in 20 Fig. 5. Cell death was induced by the ElB/19K virus which expresses both ElA products and by dlll07/ElB. Mutant AR2 / ElB which lacks AR2 also killed, but was consistently less toxic that the former viruses. other mutants affecting CR3, AR1 and the p300 binding sites failed to kill significantly during the test period.

Activation of E4 expression and apoptosis.

25

30

The requirement for ARI suggested that E4 products might somehow be involved in the induction of p53independent apoptosis as this region is not important in the activation of other early viral transcription units. Studies were therefore carried out to examine the pattern of ElA transactivation of the E4 promoter in which plasmid DNA encoding various mutants forms of ElA-289R was co-transfected into NIH-3T3 or CHO cells along with DNA from E4-CAT, a construct that encodes CAT under the control of the Ad5 E4 promoter. Table 1 shows that in addition to CR3, activation of the E4 promoter required AR1 and to some extent AR2.

AR2 (pml132)	Δ224-238	AR2	64 ± 16

* CHO or 3T3 cells were transfected with plasmid DNA 10 encoding various ElA mutants and CAT under the Ad5 E4 promoter.

Cell extracts were assayed for CAT activity as described above. The activity has been expressed as a % of that obtained with wt. Three independent assays were done for each mutant.

In addition, regions at the N-terminus and in CR1 involved in binding of p300 also were of some importance. These results closely paralleled the pattern of ElA-induced p53-independent apoptosis and suggested that E4 products might be involved.

E2 and E3 products are not required for apoptosis

It was unlikely that E2 products were responsible for the induction of p53-independent apoptosis for two reasons. First, in addition to CR3, complex formation involving CR2 and the pRB family of proteins acti-

vates E2 expression, and CR2 was shown to be of little Second, reasonably high importance in cell killing. levels of expression of E2 proteins are known to be induced by the ElA-243R protein which is completely unable to induce p53-independent apoptosis. experiments were carried out to determine if any E3 The Al.A3 mouse embryo fibroproducts were involved. blast cell line lacking p53 but expressing Ad5 ElA proteins, and Hy.A3 hygromycin-selected p53 control cells (Lowe, S.W. et al., 1994, Proc. Natl. Acad. U.S.A., 91:2026-2030), were infected with wt Ad5, the E1B/19K virus, adenovirus vector AdlacZ which contains lacZ in place of ElA and ElB, or with vector Ad5d170-8 which lacks both the entire El and E3 regions. extracts were assayed for the presence of degraded DNA as before. Fig. 6 shows that high levels of DNA degradation were induced in Al.A3 cells with the 19K mutants as well as both adenovirus vectors. Cell lines expressing 289R and 243R ElA proteins constitutively, or the Hy.A3 non-expressing control cell line, were mock-infected or infected with wt Ad5 or adenovirus vectors AdLacZ or Ad5d170-8. After 40 h, DNA was extracted and analyzed by agarose gel electrophoresis. The contents of individual lanes are as indicated in Similar results were also obtained with two other similar ElA-expressing cell lines, Al.A6 and Fig. 6 also shows that in the control cells lacking constitutive ElA expression, only the ElB/19K virus induced DNA degradation. These results indicated that E3 products were not required for induction of by BlA under these p53-independent apoptosis conditions.

E4 proteins are essential for p53-independent apoptosis

To determine directly if E4 products are
involved in the induction of cell death, as suggested

30

35

by experiments described above, two approaches were In the first, human p53 SAOS-2 cells were infected with wt Ad5 or Ad2, or with Ad2 mutant dll019 which produces no E4 proteins (Bridge, E. et al., 1989, J. Virol., 63:631-638), or they were mock-infected. Although such viruses express ElB proteins and thus are protected from ElA-induced apoptosis, it was thought that if E4 products were essential for p53-independent cell death, some difference in long term cell survival might be observed, and thus at various times up to 10 days, infected cultures were tested for cell viability. Fig. 7 shows that cells infected either by wt Ad5 or Ad2 virus began to die at about 100h p.i., and by 240h p.i. almost all of the cells were dead. SAOS-2 cells were mock-infected or infected with wt Ad5 or Ad2, or dll019 which expresses no E4 products. times up to 10 days cell viability was assessed by Trypan Blue™ exclusion. Data have been expressed as % cell viability and symbols are as indicated in the Such was not the case with dll019-infected Fig. 7. 20 cells which remained almost as viable as mock-infected cells even 10 days after infection. These results indicated that an E4 product was involved in cell killing in the absence of p53. This idea was confirmed in experiments involving infection of ElA-expressing p53 25 Al.A3 cells with the adenovirus vector AdRSVβgal.ll in which both the El and E4 regions had been completely deleted. Fig. 8 shows that in control Hy.A3 p53 cells which do not express ElA, only the ElB/19K Ad5 mutant caused DNA degradation, and neither wt , 12S/E1B , nor the AdRSVBgal.ll vector had any significant effect. Cell lines expressing 289R and 243R ElA proteins constitutively, or the Hy.A3 non-expresser control cell line, were mock-infected or infected with wt Ad5, E1B/19K, 12S/E1B, or the adenovirus vector

AdRSVBgal.il which lacks both El and E4. After 40 h, DNA was extracted and analyzed by agarose gel electrophoresis. The contents of individual lanes are as indicated in the Fig. 8. With Al.A3 cells, both the E1B/19K and 12S/E1B induced DNA degradation, but the AdRSVBgal.11 vector still had little affect. results were obtained with the other two sister cell lines, Al.A6 and Al.A12 discussed above. The ability of this virus to induce apoptosis in Al.A3 cells was analyzed further in cell killing experiments. - lines expressing 289R and 243R ElA proteins constitutively (panel A), or the Hy.A3 non-expresser control cell line (panel B), were mock-infected or infected with wt Ad5, E1B/19K, 12S/E1B, or the adenovirus vector AdRSVBgal.ll. At various times after cell viability was assessed by Trypan Blue™ exclusion. Data have been expressed as % cell viability and symbols are as indicated in the Fig. 9. Fig. 9A shows that in the Hy.A3 control cells, only the ElB/19K virus induced cell death, whereas in Al.A3 cells both the ElB/19K and 12S/E1B viruses did so. However in both cases the AdRSVBgal.ll-infected cells remained as fully viable as mock-infected cultures. These data thus confirmed that an E4 product is responsible for E1A-induced p53-independent cell death.

RESULTS AND DISCUSSION

20

25

30

35

では、100mmので

To identify which E4 product is responsible for induction of E1A-dependent p53-independent apoptosis, p53-null mouse 10(1) cells were infected with wt Ad5 or with mutants carrying deletions in various portions of the E4 region (see Fig. 10). Fig. 11 shows that as shown above, cells in cultures infected by the wt virus began to die by about 125 hours following infection, and death was almost complete by 240 hours.

10

15

20

25

Little cell death was observed in mock-infected cultures or in those infected by mutant dl1019 which lacks the entire E4 region. Cell death similar to that found with wt was observed with E4 mutants dl1013 which expresses E4orf6 and E4orf4, whereas little death occurred with mutant di1010 which expresses all E4 products except E4orf6. These results indicated that cell death occurred only when the E4orf6 protein was expressed and did not take place during the course of the experiment in its absence. Thus it is clear that expression of the E4orf6 protein is essential for the p53-independent apoptosis induced by the 289R E1A product.

It has been known for some time that adenovirus ElA products induce DNA degradation, rapid cell death and other hallmarks of apoptosis when expressed in the absence of ElB products whose major role in lytic infection and transformation is to suppress ElA toxicity. Both the 289R and 243R ElA proteins are able to induce apoptosis through p53-dependent pathways.

ElA proteins also induce apoptosis in cells lacking p53 (Teodoro, J.G., et al., 1995, Oncogene, 11:467-474). We found that this p53-independent apoptosis was elicited only by the 289R ElA protein, and preliminary evidence suggested that expression of one or more additional early viral genes regulated by ElA-289R was required. The present experiments indicated that the ElB-55kDa protein is unable to block this effect, but both the ElB-19kDa product and the cellular suppressor of apoptosis Bcl-2 significantly inhibited this response.

The major goal of this work was to identify which early viral transcription units were required to induce cell death in the absence of p53. Results obtained with EIA mutants clearly indicated the CR3 is impor-

Furthermore, CR3-mediated transactivation activity appeared to be required, as several point mutants in CR3 which were known to eliminate transactivation of target genes were defective for induction of DNA degradation and cell killing. Of great interest were results obtained with mutants with defects outside CR3. Mutant dlll08 which lacks the core binding site for pRB and related proteins induced p53-independent apoptosis like wt. However, mutant dlll01 which binds pRB at reasonably normal levels but fails to bind the p300 transcriptional modulator was totally defective. results may suggest that interactions between p300 and 289R are essential to institute cell death pathways. Another possibility was offered by results obtained with two additional mutants with defects in the AR1 and AR2 regions encoded by the second exon of the 13S ElA The AR1-defective mutant was unable to induce p53-independent apoptosis, and that lacking AR2 was somewhat impaired. These results corresponded exactly to the relative abilities of these mutant ElA molecules to transactivate the E4 promoter. We also found that dlll01 was partially defective for transactivation of E4, thus suggesting both that E4 products might be involved in induction of cell death and that interactions of 289R with p300 may reflect more a requirement for transactivation of E4 transcription than a direct role in apoptosis. This question will only be answered by further experiments using a new series of mutants.

Early regions E2, E3 and E4 encode a variety of products which could play some role in cell death. E2 proteins are largely involved in viral DNA synthesis. However, it is unlikely that any play an essential role in cell death. First, E2 transcription requires not only CR3, but also the formation of complexes with pRB which result in the activation of the E2F family of

transcription factors and E2 gene expression. results clearly indicated that complex formation with pRB was not essential for apoptosis. Second, the adenovirus vector AdRSVpgal.ll contains a wt E2 region and yet was defective for induction of p53-dependent apoptosis in ElA-expressing cells. The E3 region encodes several proteins which affect virus-host interactions, however, the adenovirus vector Ad5d170-8 was fully capable of inducing apoptosis in ElA expressing p53-deficient cells. As discussed above, the pattern of apoptosis observed with ElA mutants suggested that the early viral proteins associated with cell death are encoded by E4. Direct evidence that an E4 protein is responsible was obtained from experiments in which the pattern of death was observed in p53-null SAOS-2 cells infected by wt Ad5 or a mutant defective in E4 expres-Because ElB products were expressed by these viruses, cell death occurred only at late times, but the observation that E4 mutant-infected cells displayed considerably retarded death clearly implicated an E4 product in the death process. Final confirmation came from results with the AdRSVβgal.ll adenovirus vector which was defective for cell killing. This virus was unable to induce DNA degradation or cell killing in p53-deficient cells expressing ElA.

It is likely that the E4orf6, or the adenovirus E4 Death Protein (E4-ADP), is responsible for the ultimate death of human cells following productive infection by adenoviruses. Cell death could be induced early after infection following expression of E1A proteins, however, p53-dependent apoptosis, which is induced directly by E1A, is blocked by expression of both the 55kDa and 19kDa E1B proteins. Following expression of the E4-ADP, infected cells would die by p53-independent apoptosis were it not for the E1B-19kDa

-

product which blocks cell death until late in infection (Marcellus, S. et al.,1996, J. Virol.; in press). Cell death may eventually occur because the levels of the E4-ADP become too elevated for suppression by E1B-19K.

In addition to its role in virus infection, the E4-ADP could be of use in killing cells that accumulate in several disease states, including some auto-immune disorders and cancer. Such cells fail to die by apoptosis and, at least in many cancers, one reason is because many cancer cells lack or express a mutant form of p53. These cells would, however, be susceptible to killing by the E4-ADP. Further studies will be necessary to define the specificity of cell killing and the mechanism of induction of apoptosis by the E4-ADP.

ABSTRACT OF THE INVENTION

· 公司多用的形式的时间,所不够被虚伪有限的正式的时间

The present invention relates to a pharmaceutical agent for induction of apoptosis for the treatment of human diseases which involve inappropriate cell survival, which comprises E4orf6, an analog or a biologically active fragment thereof. There is also provided a pharmaceutical composition for the treatment of human diseases which involve inappropriate cell survival, which comprises a therapeutical amount of E4orf6, an analog or a biologically active fragment thereof in association with a pharmaceutical carrier.
